<td>○</td>
<td>○</td>
<td>○</td>
<td></td>
</tr>
</tbody>
</table>

- The total number of timers is 256 (T0~T255) with three different time bases, 0.01S, 0.1S and 1S. The default number and allocation of timers is shown as below (Can be adjusted according to user’s actual requirements by the “Configuration” function):
  - T0~T49: 0.01S timer (default as 0.00~327.67S).
  - T50~T199: 0.1S timer (default as 0.0~3276.7S).
  - T200~T255: 1S timer (default as 0~32767S).
- FBs-PLC programming tool will lookup the timer’s time base automatically according to the “Memory Configuration” after the timer number is keyed in. Timer’s time = Time base x Preset value. In the example 1 below, the time base T0 = 0.01S and the PV value = 1000, therefore the T0 timer’s time = 0.01S x 1000 = 10.00S.
- If PV is a register, then Timer’s time = Time base x register content. Therefore, you only need to change the register content to change the timer’s time. Please refer to Example 2.
- The maximum error of a timer is a time base plus a scan time. In order to reduce the timing error in the application, please use the timer with a smaller time base.

## Description

- When the time control “EN” is 1, the timer will start timing (the current value will accumulate from 0) until “Time Up” (i.e. CV ≥ PV), then the Tn contact and TUP (FO0) will change to 1. As long as the timer control “EN” input is kept as 1, even the CV of Tn has reached or exceeded the PV, the CV of the timer will continue accumulating (with M1957 = 0) until it reaches the maximum limit (32767). The Tn contact status and flag will remain as 1 when CV ≥ PV, unless the “EN” input is 0. When “EN” input is 0, the CV of Tn will be reset to 0 immediately and the Tn contact and “Time Up” flag TUP will also change to 0 (please refer to the diagram ① below).
- If the FBs-PLC OS version is higher than V3.0 (inclusive), the M1957 can be set to 1 so the CV will not accumulate further after “Time Up” and stops at the PV value. The default value of the M1957 is 0, therefore the status of M1957 can be set before executing any timer instruction in the program to individually set the timer CV to continue accumulating or stop at the PV after “Time Up” (please refer to the diagram ② below).
Example 1  Constant preset value

An example of taking "Time-Up" signal directly from FO0.

Example 2  Variable PV

The preset value (PV) shown in example 1 is a constant which is equal to 1000. This value is fixed and can not be changed once programmed. In many circumstances, the preset time of the timers needs to be varied while PLC running. In order to change the preset time of a timer, can first use a register as the PV operand (R or WX, WY...) and then the preset time can be varied by changing the register content. As shown in this example, if set R0 to 100, then T becomes a 10S Timer, and hence if set R0 to 200, then T becomes a 20S Timer.
**An example of applying the “time-up” status by using the T50 contact.**

**Remark:** If the preset value of the timer is equal to 0, then the timer's contact status and FO0 (TUP) become 1 ("EN" input must be at 1) immediately after the PLC finishes its first scan because "Time-Up" has occurred. (TUP) stays at 1 until "EN" input changes to 0.
There are total 200 16-Bit counters (C0~C199). The range of preset value is between 0~32767. C0~C139 are Retentive Counters and the CV value will be retained when the PLC turns on or RUN again after a power failure or a PLC STOP. For Non Retentive Counters, if a power failure or PLC STOP occurs, the CV value will be reset to 0 when the PLC turns on or RUN again.

There are total 56 32-Bit counters (C200~C255). The range of the preset value is between 0~2147483647. C200~C239 are Retentive Counters and C240~C255 are Non Retentive Counters.

The default number and assignment of the counters are shown below, if necessary can use the "CONFIGURATION" function to change the settings.

To insure the proper counting, the sustain time of input status of CLK should greater than 1 scan time.

The max. counting frequency with this instruction can only up to 20Hz, for higher frequency please use the high-speed soft/hardware counter.

When "CLR" is at 1, all of the contact Cn, FO0 (CUP), and CV value of the counter CV are cleared to 0 and the counter stops counting.

When "CLR" is at 0, the counter is allowed to count up. The Counter counts up every time the clock "CK ↑ " changes from 0 to 1 (adds 1 to the CV) until the cumulative current value is equal to or greater than the preset value (CV>=PV), the counter "Count-Up" and the contact status of the counter Cn and FO0 (CUP) changes to 1. If the input status of clock continues to change, even the cumulative current value is equal and greater than the preset value, the CV value will still accumulate until it reaches the up limit at 32767 or 2147483647. The contact Cn and FO0 (CUP) stay at 1 as long as CV>=PV unless the "CLR" input is set to 1. (please refer the diagram ① below).

If the FBs-PLC OS version is higher than V3.0 (inclusive), the M1973 can set to 1 so the CV will not accumulate further after “Count Up” and stops at the PV. M1973 default value is 0, therefore the status of M1973 can be set before executing any counter instruction in the program to individually set the counter CV to continue accumulating or stops at the PV after “Count Up” (please refer to the diagram ② below).
Basic Function Instruction

### Example 1
#### 16-Bit Fixed Counter

#### Ladder Diagram
- **Ladder diagram**

#### Key Operations
- **Mnemonic code**

#### Mnemonic Code
- ORG SHORT
- RST M 1973
- ORG X 0
- LD X 1
- C 1 PV: 5
- FO 0
- OUT Y 1
- ORG SHORT
- SET M 1973
- ORG X 0
- LD X 1
- C 2 PV: 5

#### An example of applying the “Count-Up” status by using FO0 directly.

#### Diagram

1. **M1973=0**
   - (Defaulted)
   - Count Start Count-Up
   - X0: 0, 1, 2, 3, 4, 5, 6
   - X1: 0
   - Y1: 5 times

2. **M1973=1**
   - Count Start Count-Up
   - X0: 0, 1, 2, 3, 4, 5
   - X1: 0
   - Y1: 32767 times

#### Example 2
#### 32-Bit counter with variable preset value

- Like a timer, if the PV of a counter is changed to a register (such as R, D, and so on), the counter will use the register contents as the counting PV. Therefore, only need to change the register contents to change the PV of the counter while PLC is running. Below is an example of a 32-bit counter that uses the data register R0 as the PV (in fact it is the 32-bit PV formed by R1 and R0).
COUNTER
(16-Bit: C0～C199, 32-Bit: C200～C255)

Ladder diagram

<table>
<thead>
<tr>
<th>Key operations</th>
<th>Mnemonic code</th>

Basic Function Instruction

### Description

- There are a total of 128 MC loops (N=0~127). Every Master Control Start instruction, MC N, must correspond to a Master Control End instruction, MCE N, which has the same loop number as MC N. They must always be used in pairs and you should also make sure that the MCE N instruction is after the MC N instruction.
- When the Master Control input "EN/" is 1, then this MC N instruction will not be executed, as it does not exist.
- When the Master Control input "EN/" is 0, the master control loop is active, the area between the MC N and MCE N is called the Master Control active loop area. All the status of OUT coils or Timers within Master Control active loop area will be cleared to 0. Other instructions will not be executed.

### Example

<table>

</tr>
<tr>
<td>X1</td>
<td></td>
<td>OUT Y 2</td>
</tr>
</tbody>
</table>
Remark1: MC/MCE instructions can be used in nesting or interleaving as shown to the right:

Remark2: • When M1918=0 and the master input changes from 0→1, and if pulse type function instructions exist in the master control loop, then these instructions will have a chance to be executed only once (when the first time the master control input changes from 0→1). Afterwards, no matter how many times the master control input changes from 0→1, the pulse type function instructions will not be executed again.
  • When M1918=1 and the master control input changes from 0→1, and if pulse type function instructions exist in the master control loop, then each time the master control input changes from 0→1 the pulse type function instructions in the master control loop will be executed as long as the action conditions are satisfied.
  • When a counting instruction exists in the master control loop, set M1918 to 0 can avoid counting error.
  • When the pulse type function instructions in the master control loop must act upon the 0→1 input change by the master control, the flag M1918 should be set to 1.
Basic Function Instruction

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Operand</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Ladder symbol" /></td>
<td>N: Master Control End number (N=0~127) N cannot be used repeatedly.</td>
</tr>
</tbody>
</table>

### Description

- Every MCE N must correspond to a Master Control Start instruction. They must always be used as a pair and you should also make sure that the MCE N instruction is after the MC N instruction. After the MC N instruction has been executed, all output coil status and timers will be cleared to 0 and no other instructions will be executed. The program execution will resume until a MCE instruction which has the same N number as MC N instruction appears.

- MCE instruction does not require an input control because the instruction itself forms a network which other instructions can not connect to it. If the MC instruction has been executed then the master control operation will be completed when the execution of the program reaches the MCE instruction. If MC N instruction has never been executed then the MCE instruction will do nothing.

### Description

- Please refer to the example and explanations for MC instruction.
**Basic Function Instruction**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Operand</th>

</thead>
<tbody>
<tr>
<td>Ladder symbol</td>
<td>N: Skip loop number (N=0~127),</td>
</tr>
<tr>
<td></td>
<td>N can not be used repeatedly.</td>
</tr>
</tbody>
</table>

**Description**

- There are total 128 SKP loops (N=0~127). Every skip start instruction, SKP N, must correspond to a skip end instruction, SKPE N, which has the same loop number as SKP N. They must always be used as a pair and you should also make sure that the SKPE N instruction is after the SKP N instruction.

- When the skip control "EN" is 0, then the Skip Start instruction will not be executed.

- When the skip control "EN" is 1, the range between the SKP N and SKPE N which is so called the Skip active loop area will be skipped, that is all the instructions in this area will not be executed. Therefore the statuses of the discrete or registers in this Skip active loop area will be retained.

![Diagram showing the timing and sequencing of functions and skips in a control system.](image-url)

- **X0**: Represents the initial state.
- **X1**: Follows after a delay of 10 units.
- **X2**: Further delay of 10 units compared to X1.
- **T201**: Shows a cumulative delay of 10 units.
- **Y0**: skips after a delay of 10 units.
- **Y1**: Skips after a delay of 10 units, following X2.
- **Y2**: Skips after a delay of 10 units, following Y1.

The diagram illustrates how delays and skips are managed in the control system, ensuring accurate timing and operation between different components.
### Symbol

**Ladder symbol**

<table>
<thead>
<tr>
<th>SKPE</th>
<th>N</th>
</tr>
</thead>
</table>

### Operand

**N** : SKIP END Loop number (N=0~127) 

Can not be used repeatedly.

### Description

- Every SKPE N must correspond to a SKP N instruction. They must always be used as a pair and you should also make sure that the SKPE N instruction is behind the SKP N instruction.

- SKPE instruction does not require an input control because the instruction itself forms a network which other instructions can not connect to it. If the SKP N instruction has been executed then the skip operation will be completed when the execution of the program reaches the SKPE N instruction. If SKP N instruction has never been executed then the SKPE instruction will do nothing.

### Example

- Please refer to the example and explanations for SKP N instruction.

**Remark** : SKP/SKPE instructions can be used by nesting or interleaving. The coding rules are the same as for the MC/MCE instructions. Please refer to the section of MC/MCE instructions.
### Basic Function Instruction

#### Symbol

- **Ladder symbol:**
  - Input status → TGU
  - DIFU
  - D

- **Operand:**
  - D: a specific coil number where the result of the Differential Up operation is stored.

<td>○</td>
<td>○</td>
<td>○</td>
<td>○</td>
</tr>
</tbody>
</table>

#### Description

- The DIFU instruction is used to output the up differentiation of a node status (status input to "TGU") and the pulse signal resulting from the status change at the rising edge of the "TGU" for one scan time is stored to a coil specified by D.

- The functionality of this instruction can also be achieved by using a TU contact.

#### Example

</table>

**t:** scan time
The DIFD instruction is used to output the down differentiation of a node status (status input to "TGD") and the pulse signal resulting from the status change at the falling edge of the "TGD" for one scan time is stored to a coil specified by D.

The functionality of this instruction can also be achieved by using a TD contact.

The results of the following two samples are exactly the same
**Basic Function Instruction**

**FUN 6**

**BSHF**

(Shifts the data of the 16-bit or 32-bit register to left or to right by one bit)

**Symbol**

- **Ladder symbol:**
  - **Shift control—EN:**
  - **Fill-in bit—INB:**
  - **Shift direction—L/R:**
  - **Clear control—CLR:**

- **Operand:**
  - **D:** The register number for shifting
  - **OTB:** Shift-out bit (FO0)

**Description**

- When the status of clear control "CLR" is at 1, then the data of register D and FO0 will all be cleared to 0. Other input signals are all in effect.
- When the status of clear control is "CLR" at 0, then the shift operation is permissible. When the shift control "EN" = 1 or from 0 → 1 (P instruction), the data of the register will be shifted to right (L/R=0) or to left (L/R=1) by one bit. The shifted-out bit (MSB when shift to left and LSB when shift to right) for both cases will be sent to FO0. The vacated bit space (LSB when shift to left and MSB when shift to right) due to shift operation will be filled in by the input status of fill-in bit "INB".

**Example**

**Shifts the 16-bit register data**

**Operand**

- **Y0**

**Example**

- **X3=1** (Left shift)
  - Shifts the 16-bit data to left by one bit

- **X3=0** (Right shift)
  - Shifts the 16-bit data to right by one bit
When the clear control “CLR” is 1, the counter’s CV will be reset to 0 and the counter will not be able to count.

When the clear control “CLR” is 0, counting will then be allowed. The nature of the instruction is a P instruction. Therefore, when the count-pulse “PLS” is from 0→1 (rising edge), the CV will increased by 1 (if U/D=1) or decreased by 1 (if U/D=0).

When CV=PV, FO0 (“Count-Up”) will change to 1”. If there are more clocks input, the counter will continue counting which cause CV ≠ PV. Then, FO0 will immediately change to 0. This means the “Count-Up” signal will only be equal to 1 if CV=PV, or else it will be equal to 0 (Care should be taken to this difference from the “Count-Up” signal of the general counter).

The upper limit of up count value is 32767 (16-bit) or 2147483647 (32-bit). After the upper limit is reached, if another up count clock is received, the counting value will become -32768 or -2147483648 (the lower limit of down count).

The lower limit of down count value is -32767 (16-bit) or -2147483647 (32-bit). After the lower limit is reached, if another down count clock is received, the counting value will become 32768 or 2147483648 (the upper limit of up count).

If U/D is fixed as 1, the instruction will become a single-phase up count counter. If U/D is fixed as 0, the instruction will become a single-phase down count counter.
## Up/Down Counter

### Key Operations

- **ORG** : X 18
- **LD** : X 17
- **LD** : X 16
- **FUN** : 7
- **CV** : R 0
- **PV** : -3
- **FO** : 0
- **OUT** : Y 0

### Mnemonic Codes

- **ORG**
- **LD**
- **FUN**
- **OUT**

### Remark 1

Since the counting operation of UDCTR is implemented by software scanning, therefore if the clock speed is faster than the scan speed, lose count may then happen (generally the clock should not exceed 20Hz depending on the size of the program). Please use the software or hardware high-speed counter in the PLC. Refer to the "High Speed Counter Application" in the Advanced Manual.

### Remark 2

In order to ensure the proper counting, the sustain time of the status of clock input should greater than 1 scan time.

### Description

Performs the addition of the data specified at Sa and Sb and writes the results to a specified register D when the add control input "EN" = 1 or from 0 to 1 (P instruction). If the result of addition is equal to 0 then set FO0 to 1. If carry occurs (the result exceeds 32767 or 2147483647) then set FO1 to 1. If borrow occurs (adding negative numbers resulting in a sum less than -32768 or -2147483648), then set the FO2 to 1. All the FO statuses are retained until this instruction is executed again and overwritten by a new result.

### Basic Function Instruction

**Fun 13 DF**

(Performs multiplication of the data specified at Sa and Sb and stores the result in D)

**Multiplier**

- **Sa**: Multiplicand
- **Sb**: Multiplier
- **D**: Destination register to store the results of the multiplication.

**Symbols**

- Ladder symbol: 13DP(*)

**Operand**

- Multiplication control — EN
- Unsing/Sign — U/S

**Description**

- Performs the multiplication of the data specified at Sa and Sb and writes the results to a specified register D when the multiplication control input "EN" = 1 or from 0 to 1 (P instruction). If the product of multiplication is equal to 0 then set FO0 to 1. If the product is a negative number, then set FO1 to 1.

**Example 1** 16-bit multiplication

### Description

- Performs the division of the data specified at Sa and Sb and writes the quotient and remainder to registers specified by register D when the division control input “EN” = 1 or from 0 to 1 (P instruction). If the quotient of division is equal to 0 then set FO0 to 1. If the divisor Sb = 0 then set the error flag FO1 to 1 without executing the instruction.

Adds 1 to the register **D** when the increment control input "EN" =1 or from 0 to 1 ( **P** instruction). If the value of **D** is already at the upper limit of positive number 32767 or 2147483647, adding one to this value will change it to the lower limit of negative number -32768 or -2147483648. At the same time, the overflow flag **FO0** (**OVF**) is set to 1.

**Example**

Compares the data of 16-bit register

- From the above example, we first assume the data of R0 is 1 and R1 is 2, and then compare the data by executing the CMP instruction. The FO0 and FO1 are set to 0 and FO2 (\( a < b \)) is set to 1 since \( a < b \).
- If you want to have the compound results, such as \( \geq, \leq, < > \) etc., please send \( =, < \) and \( > \) results to relay first and then combine the result from the relays.
- \( M1919=0 \), when this command in not executed, FO0, FO1, FO2 will remain in the status at last execution.
- \( M1919=1 \), when this command in not executed, FO0, FO1, FO2 are all cleared to 0.
- Control M1919 properly to obtain memory-holding function for functional command output.
Performs logical AND operation for the data of Sa and Sb when the operation control input "EN" =1 or from 0 to 1 (P instruction). This operation compares the corresponding bits of Sa and Sb (B0~B15 or B0~B31). The bit in the D is set to 1 if both of the corresponding bits data of Sa and Sb is 1. The bit in the D is set to 0 if one of the corresponding bits is 0.

#### Example

Performing logical OR operation for the data of Sa and Sb when the operation control input "EN" = 1 or from 0 to 1 (P instruction). This operation compares the corresponding bits of Sa and Sb (B0~B15 or B0~B31). The bit in the D is set to 1 if one of the corresponding of Sa or Sb is 1. The bit in the D is set to 0 if both of the corresponding bits of Sa and Sb is 0.

FB-PLC uses binary code to store and to execute calculations. If want to send the internal PLC data to the external displays such as seven-segment displays, it is more convenient for us to read the result on screen by converting the BIN data to BCD data. For example, it is more clear for us to read the reading "12" instead of the binary code "1100."

Converts BIN data of the device specified at S into BCD and writes the result in D when the operation control input "EN" = 1 or from 0 to 1 (P instruction). If the data in S is not a BCD value (0~9999 or 0~9999999), then the error flag FO0 is set to 1 and the old data of D are retained.

- The decimal (BCD) data must be converted to binary (BIN) data first in order for PLC to accept the data which is originally in decimal unit (BCD code) inputted from external device such as digital switch because the BCD data can not be accepted by PLC for its operations.
- Converts BCD data of the device specified at S into BIN and writes the result in D when the operation control input "EN" = 1 or from 0 to 1 (P instruction). If the data in S is not in BCD, then the error flag FO0 is set to 1 and the old data of D are retained.
- Constant is converted to BIN automatically when store in program and can not be used as a source operand of this function.
